

Package: SemiEstimate (via r-universe)

September 2, 2024

Title Solve Semi-Parametric Estimation by Implicit Profiling

Version 1.1.4

Description Semi-parametric estimation problem can be solved by two-step Newton-Raphson iteration. The implicit profiling method<[arXiv:2108.07928](https://arxiv.org/abs/2108.07928)> is an improved method of two-step NR iteration especially for the implicit-bundled type of the parametric part and non-parametric part. This package provides a function semislv() supporting the above two methods and numeric derivative approximation for unprovided Jacobian matrix.

*Solve Semi-parametric estimation by implicit profiling***Description**

Solve Semi-parametric estimation by implicit profiling

Usage

```
semislv(
  theta,
  lambda,
  Phi_fn,
  Psi_fn,
  jac = list(),
  intermediates = list(),
  method = "implicit",
  diy = FALSE,
  control = list(max_iter = 100, tol = 0.001),
  save = list(time = TRUE, path = FALSE),
  ...
)
```

Arguments

<code>theta</code>	the initial value of parametric part
<code>lambda</code>	the initial value of non-parametric part
<code>Phi_fn</code>	the equation function highly relevant to the parametric part
<code>Psi_fn</code>	the equation function highly relevant to the non-parametric part
<code>jac</code>	a list containing some of derivative info of <code>Phi_der_theta_fn</code> , <code>Psi_der_theta_fn</code> , <code>Phi_der_lambda_fn</code> , <code>Psi_der_lambda_fn</code> ,
<code>intermediates</code>	a list containing the important variables for diy mode
<code>method</code>	"implicit" or "iterative"
<code>diy</code>	a bool value to decide to parse user designed function
<code>control</code>	a list like <code>list(max_iter = 100, tol = 1e-3)</code> to control the early stop
<code>save</code>	a list like <code>list(time = FALSE, path = FALSE)</code> to control saving setting
<code>...</code>	static parameter for <code>Phi_fn</code> , <code>Psi_fn</code> . Diy execution function.

Value

A save space containing final iteration result and iteration path

Examples

```

Phi_fn <- function(theta, lambda, alpha) 2 * theta + alpha * lambda
Psi_fn <- function(theta, lambda, alpha) 2 * lambda + alpha * theta
# build quasi jacobiean by package NumDeriv
res <- semislv(1, 1, Phi_fn, Psi_fn, alpha = 1)
res <- semislv(1, 1, Phi_fn, Psi_fn, method = "iterative", alpha = 1)
# parsing all mathematical Jacobian function by user
res <- semislv(1, 1, Phi_fn, Psi_fn, jac = list(
    Phi_der_theta_fn = function(theta, lambda, alpha) 2,
    Phi_der_lambda_fn = function(theta, lambda, alpha) alpha,
    Psi_der_theta_fn = function(theta, lambda, alpha) alpha,
    Psi_der_lambda_fn = function(theta, lambda, alpha) 2
), method = "implicit", alpha = 1)
res <- semislv(1, 1, Phi_fn, Psi_fn, jac = list(
    Phi_der_theta_fn = function(theta, lambda, alpha) 2,
    Psi_der_lambda_fn = function(theta, lambda, alpha) 2
), method = "iterative", alpha = 1)
# parsing partial mathemetical user-provided Jacobian, the rest will be generated by the NumDeriv
res <- semislv(1, 1, Phi_fn, Psi_fn,
    jac = list(Phi_der_theta_fn = function(theta, lambda, alpha) 2),
    method = "implicit", alpha = 1
)
res <- semislv(1, 1, Phi_fn, Psi_fn,
    jac = list(Phi_der_theta_fn = function(theta, lambda, alpha) 2),
    method = "iterative", alpha = 1
)
# use some package or solve the updating totally by the user
# Cases: (1) use thirty party package (2) save the intermediates
# use diy = True, then the package will be just a wrapper for your personalise code
# diy is an advanced mode for researchers, see more examples in our vignette documents
